Geography of the Baltimore Drug Trade

Mapping Urban Youth Vulnerability and its Relationship to Crime and Environmental Inf uences

Geography & Environmental Systems Department

Study Background

Research Question •

What is the spatial social vulnerability of Baltimore's youth to employment in the open-street drug market, and how does vulnerability correlate to crime and/or suggested positive and negative environmental inf uences?

Project Motivation •

Having grown up and lived in the Baltimore area my entire life, I've gained an appreciation for the city and a personal concern for it's problems. In order to ef ectively tackle the city's drug and poverty backed decay, a new, spatially aware approach must be implemented. Efective analysis results can assist with policymaking, policing tactics, and community revitalization. For example, by locating vulnerable, high crime and/or decaying edge regions, targeted funding can help prevent the spread of problems and possibly promote rejuvenation.

Literature Review •

Studies on troubled youth and youth substance abuse suggest that social factors including peers and family composition are heavily infuential for vulnerability. Economic factors such as household income and property value, and education factors such as chronic absence and employment are indirect but also valuable.

Studies on crime suggest a high correlation to social vulnerability, and that community ownership greatly reduces social and environmental decay. Illegal drug market growth generates other direct crime such as vandalism and illegal possession and use of weapons. Markets are usually fixed with access to high trafic.

Methodology

Social Vulnerability •

Demographic and housing data is gathered and cleaned. Linear regression and spatial autocorrelation tools remove redundant variables. Using myStat, a principal component factor analysis is run to generate variable weights.

Crime Analysis •

2012 and 2013 narcotics and violent of ense* arrest data, and victim-based crime data is gathered, cleaned and normalized by area and population. Using spatial autocorrelation, based on z-values, hot spot analysis is conducted with an appropriate distance band of 450ft.

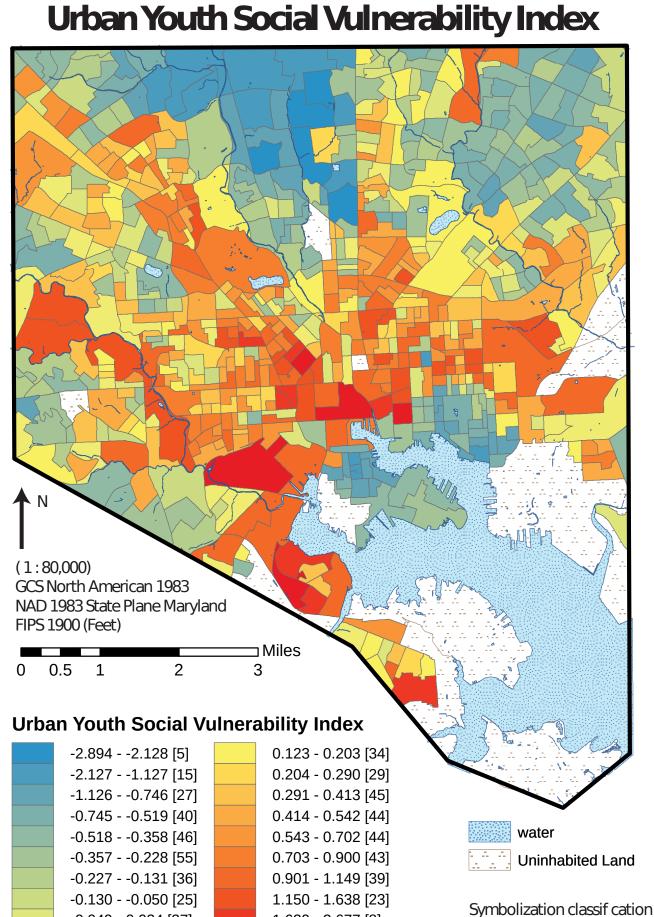

Environmental Analysis •

Positive and negative environmental factor data gathered, cleaned and aggregated to the block-group level by raw count and density.*

Vulnerability Index Without Outliers

Total Vacant Parcel Houses & Lots

Residual Results for Correlation Tests

Based on the residual results from the crime and environmental OLS linear regression model, the respective correlations to social vulnerability cannot be determined. Spatial autocorrelation suggest missing data or a lack of statistical relevance.

Discussion

Analysis of Results •

Visually, moderately high (0.5 - 0.75) to high (0.75 +) social vulnerability can be observed in downtown, directly west and north west of Martin Luther King Jr. Blvd, following Park Heights Ave, and along the west and southwest side of Gwynns Falls. On the east side, high vulnerability occurs in pockets directly southeast and east of I-83, east of Johns Hopkins Medical Campus, and surrounding east North Ave. Crime hot spots occur in similar areas with multiple types havily concentrated northeast of Patterson Park, along Pennysylvania Ave, around Pimlico, and within Pratt Monroe. Vacancies occur most heavily near by including Greenmount and Lexington Terrace.

After running spatial autocorrelation tests on residuals of several linear regression models to determine correlation between observed factors, high z-scores such as 11.415, 10.986 and 13.526 suggest unreliable results. These scores resulted when testing social vulnerability against crime normalized by area, by population, and against total vacant parcels respectively. Although these results aren't statistically relevant, visually, levels of high correlation are apparent. Low social vulnerability (>=-1) often occur in low crime and low vancany areas including Federal Hill, Canton, the wedge of wealth, and Upper Hamilton. On the contrary, Greenmount, Broadway East, Upton and Pratt Monroe show high crime, vacancy and vulnerability (>= .75).

Limitations •

Project biases occurred from aggregation and interpolation of missing data gathered from multiple sources including the U.S. Census, Open Baltimore and BNIA. Primary source data biases occurred from unquantif able and subjective values such as the absence of census data on unrecorded illegal drug purchases, and unequal police patrol routes and arrests, respectively. Improper data analysis and/or categorization prevented any statistically relevant results, limiting further analysis.

Condusion

Project Findings •

Baltimore's urban youth social vulnerability has a normal bell curve distribution with a slight skew right towards higher vulnerability. Many social vulnerability indicators can be applied when observing youth, allowing for fairly simple project adjustments and extensions. However, in order to observe accurate variations, it's essential that social vulnerability data be aggregated to no larger than the block-group level. Based on results, attention should be paid to the neighborhoods along east North Ave, Pennsylvania Ave and the Gwynns Falls corridor from Edmonson Ave to Wilkens Ave.

Future Work •

Statistical analysis was limited due to experience and time restraints. To better examine youth social vulnerability, more youth specific variables should be tested such as school test scores, after school involvement and community involvement. In addition, crime analysis can be aggregated to street block level, and should be separated by of ense type and age categories. Observing positive environmental factors, like rec community centers, may show a positive and/or stronger correlation with vulnerability.
